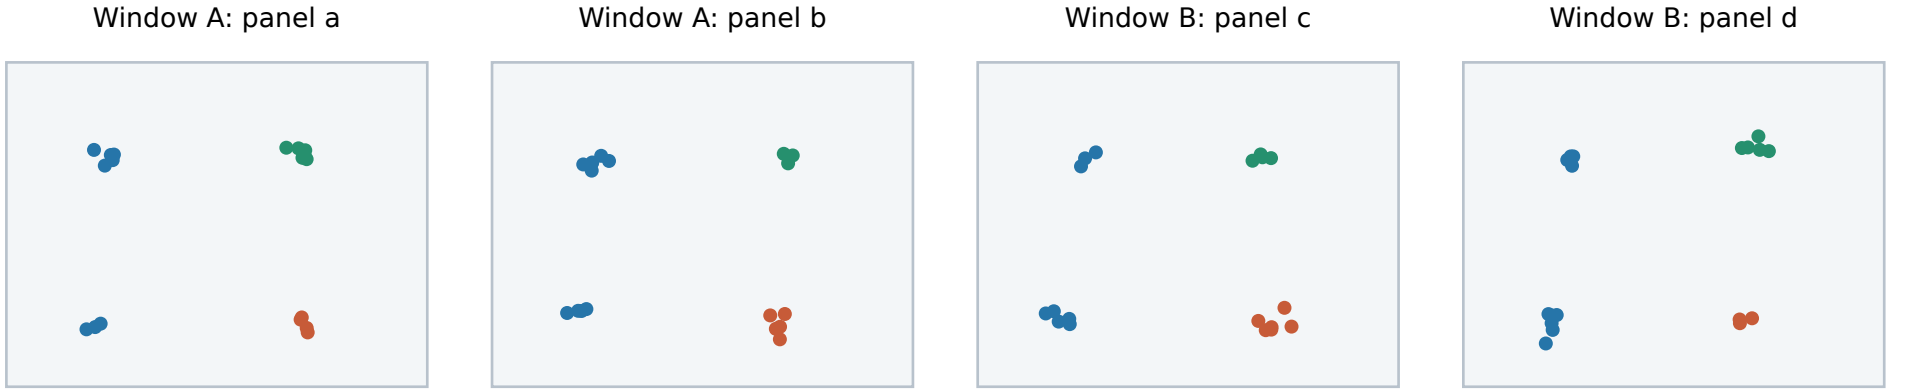
a Permanent source codes, unequal counts, disjoint panels



One code per persistent source; different sources may share a code.

b Match the count product

$R_A = E\,\mathrm{Re}\,H_3(Z_a, \overline{Z_b}, n_c)$

$C_A = \frac{1}{2}E\,\mathrm{Re}\,[H_3(Z_a, n_b, \overline{Z_c})$

$\quad + H_3(n_a, Z_b, \overline{Z_c})]$

$w_s = n_{sa}n_{sb}n_{sc}$ in both moments

$C_A = a(q)R_A$ under the stated model

c Separate normalization can retain bias

$R_2 = \sum_s u_s k_s, \quad C_2 = a(q)\sum_s v_s k_s$

$C_2/R_2 = a(q)\,\frac{\sum_s v_s k_s}{\sum_s u_s k_s}$

Kernel invariance for every admissible $k_s > 0$

holds exactly when $u_s = v_s$ for all sources.

A population identity, not a physical certificate.
